Time to return to baseline level was the number of days since treatment until the first visit at which IGA-FWS and PFWS scores had both returned to baseline levels after an improvement from baseline had been observed at week 1, 2, or 4. If no such return to baseline level occurred, censoring occurred at the latest visit for which both IGA-FWS and PFWS data were available. In the absence of an improvement in both IFA-FWS and PFWS scores at weeks 1, 2 or 4, the time to return to baseline was 0 days.
